IDENTIFICATION OF TECHNOLOGY INTEGRATION CHALLENGES AT TWO GLOBAL AUTOMOTIVE OEMS

I. Alonso Fernández , M. Panarotto and O. Isaksson

Chalmers University of Technology, Sweden

 inigo.alonso@chalmers.se

Abstract

Platform design has been firmly established in the automotive industry as a strategy to provide wider product variety while maintaining cost effective production. But this strategy can struggle to keep up with the pace and nature of emerging technologies. This paper reviews the existing approaches to modelling product platforms, and showcases the challenges at OEMs introducing new technological innovations in their platforms. A gap is identified in the methods to assess the ability of existing platforms to integrate new technologies whenever they become available.

Keywords: *product platform, technology development, product architecture, decision making, innovation*

1. Introduction

The automotive industry is a highly competitive, low-margin industry, and manufacturers face an ever-increasing pressure to maintain the margin between their revenues and costs. For years, the industry has developed strategies and organisations that maximise the diversity of their offerings to meet individual customer's needs in a global market, while keeping the cost of realization minimal.

A car, nowadays consisting of tens of thousands of components, or a truck, theoretically allowing up to 10^{200} individual combination opportunities (Schroeder et al., 2016), demand clear strategies for balancing the number of allowable set of variants to be produced to be able to cope with the combinatorial explosion of possibilities. One of these strategies is the use of product platforms (Jiao et al., 2007), where most car manufacturers and truck manufacturers have established their own ways of defining a platform.

This work presents an in-depth study of two use cases on the present challenges perceived inside the development organisation at two automotive Original Equipment Manufacturers (OEMs) (Volvo Car Group, VCG, and Volvo Group Truck Technology, VGTT), when assessing and evaluating how to integrate next generation technologies in their existing platforms.

Figure 1. Industrial cases from VGTT (left) and VCG (right)

VCG manufactures and markets luxury cars, and VGTT participates in the development of trucks distributed in more than 190 markets world-wide by different brands (e.g. Volvo Trucks, Renault Trucks, Mack, UD Trucks). The current use case explored with VCG was a digital information display system, and in the case of VGTT a cabin subsystem, including environment sensors.

Several variants of a certain vehicle are based on the same platform, and often this platform is expected to last for up to a decade to recover the R&D cost incurred in its development.

At the same time, there are several radical technological transformations underway, including the introduction of increasingly autonomous vehicles, the replacement of conventional internal combustion powertrains with electrical, hybrid or hydrogen powered alternatives, and the shift into digital solutions that replace classical, mechanical or electro-mechanical, functions in the vehicles. Also, materials, manufacturing methods, and assembly processes are experiencing radical changes. In many cases, the platform architecture and its interfaces are challenged, and important questions arise.

- What challenges are encountered at automotive manufacturers when trying to generate value by integrating new technologies into established product platforms?

Platform based development by enforcement of compliance with an existing structure (architecture) in the automotive sector, may limit innovation and the adoption of new emerging technologies. Unless the consequence and impact on the existing platform of a new technology can be clarified and understood, the risk of introducing such technology may remain too high. The phase of the design process where technology integration options are considered, elaborated and judged needs to be aptly supported.

1.1. Context and gaps

[Meyer and Lehnerd \(1997\)](#) define a product platform as ‘a set of subsystems and interfaces that form a common structure from which a stream of derivative products can be efficiently developed and produced’. A technology is defined as the body of knowledge the design, development and manufacture of the product relies on ([Brusoni et al., 2001](#)).

Products are becoming increasingly multi-technological ([Patel and Pavitt, 1997](#)), relying on specific but different technologies to fulfil their functions and to be manufactured. The behaviour of the product as a system is largely determined by the combined characteristics governed by the constituent components and their interrelations. Integrating new technologies as they reach a certain maturity status is thus becoming a more pressing decision.

The product development cycles in the automotive industry are driven by a market demanding new models on a more frequent basis (market pull), and the parallel development of new technologies (technology push) that are rapidly demanded and expected by the customers, e.g. in the ICT sector. Automotive OEMs offer fundamentally standardized products, which makes them try to differentiate their brands by offering a wide diversity of options and upgrades to their base models. Additionally, more and more restrictive environmental regulations are also forcing OEMs to have to adapt and evolve their products. The introduction of architectural frameworks in the context of software and electronics has been described ([Eklund et al., 2005](#)), as well as the challenges of software architecting in the automotive domain ([Eliasson et al., 2015](#)). The use of standardized layouts to support variant management in the automotive sector was proposed by [Förg et al. \(2014\)](#) and [Stocker et al. \(2016\)](#).

Big groups of multidisciplinary experts are tasked with fulfilling some dynamic business goals by coordinating their efforts and making the best decisions with the information available. The expected rate of launching new models and variants in combination with ever increasing variety of technologies to integrate (e.g. electronics, software, new materials...) create a true challenge for early phase design. This difficulty to integrate new technologies to expand a product family has been brought up in the literature ([Halman et al., 2003](#)).

Based on these considerations, this work reports on the challenges encountered when introducing a new technology into a product derived from a platform, and it advances our understanding of the current practice. This study contributes to the description of the “as is” status of industrial practice and the analysis of the current challenges and trends. It also provides an initial contribution to an

upcoming prescriptive study, proposing the introduction of a model-based method to support early decision making in the platform development process.

2. Method

The study fulfils the role of a Research Clarification (RC) study within the Design Research Methodology (DRM) framework (Blessing and Chakrabarti, 2009). It combines a review of the literature with an empirical study, using industrial use cases from two OEMs (VGTT and VCG).

The literature review process was iterative and was composed of the generic activities of formulating the research question, searching the extant literature, screening for inclusion, assessing the quality of the results, extracting data and analysing data (Templier and Paré, 2015). Some of these activities were launched in the planning stages of the study and all of them were refined in later phases.

In the industrial use cases, a total of twenty-eight participants from the two OEMs, with an average experience in the automotive industry of 17.32 years (SD = 8.3) and spanning across all the disciplines involved in the development of a new product were involved. The roles of the participants are listed in Table 1. They were proposed by each of the internal functions of the companies.

Table 1. Roles of participants

VGTT	VCG
VP Technology Cab	Product Owner
Global Platform Manager	Lead Engineer
Group Manager	Portfolio Manager
CAB Engineering Task Leader	UX Architect
Lead Engineer	Attribute Leader Ergonomics
Product Development	Attribute Leader Service
Cab Platform Architect	Attribute Leader Safety
Product Planning	Principal Engineer Solidity
Active Safety	Expert Studio Engineer
Climate System	Cockpit Integration
Passive Safety Technology Specialist	Mechanical Integration
Crash and Safety Simulation Engineer	Manufacturing Engineer
GTM Cab Exterior	System Manufacturing Engineer
Technical Specialist Physical Ergonomics	
Front Underrun Protection	

The use cases were selected in collaboration with the manufacturers, aiming for systems with interfaces to many different stakeholders. To guide both the workshops and interviews, a questionnaire was used. The questionnaire was divided in two parts, the first focusing on the experience of the participants in previous introductions of a new technology, and the second focused on the current challenges with the selected use case. The questions, summarized in 0, were accompanied by brief explanations and examples, and were answered in free form text format.

Table 2. Summary of questionnaire

First part
Identify some situation in the past where the integration of a new technology caused some issues
What were the consequences of not being able to solve these issues?
What engineering aspects impacted these issues?
Second part
Identify your expectations regarding the integration of [the current use case]
What would be the consequences if those expectations are not met?
What engineering aspects will impact these expectations?

The procedure followed during the workshops was to first reflect on previous experiences, and then to discuss with the rest of the group the experiences of each of the individuals and add or refine the answers to the questionnaire. Using groups enables a more varied elicitation plus it allows for management to observe (Ulrich and Eppinger, 2012). The second part involved reflecting on the current issues being encountered and recording everyone's expectations regarding the use case. Finally, the use case and the expectations of all the stakeholders were discussed in the group, and the questionnaire was finalized with any additional insight. Two individual interviews were held following an equivalent semi-structured procedure, to ensure all disciplines with a stake in the project (as judged by the project leaders) were represented in the dataset, and to avoid relying on opportunistic inputs.

The workshops took around three hours to complete each, and the semi-structured individual interviews around one hour each. The analysis of the data was carried out in two stages. During the pre-processing stage, the answers were transcribed from the hand-written questionnaires into a spreadsheet, cleaned typos and spelling mistakes, expanded acronyms, and verified the cleaned-up dataset with the stakeholders. The main analysis consisted in the categorization of data, by coding the drivers of change, constraints and challenges discussed by the participants.

Relying solely on interviews can limit the completeness of the dataset. A more complete dataset may be obtained by observing model use in the design process with observations and ethnography methods. Observation is however extremely demanding of research resources when decision processes span a long-time period (Mintzberg et al., 1976). Therefore, we were obliged to rely heavily on interviews. Furthermore, tapping the memories of decision-makers can introduce errors of memory failure, as well as a risk of 'recall vs. reality' where people often overly rationalise their own viewpoints. These limitations were approached by asking the interviewees beforehand to relate as much as possible of their last completed project so that these situations remained fresh in their minds.

3. Results

3.1. Literature review

The literature around product platforms is abundant. The state of the art on product platform design methods and tools was summarized by Jiao et al. (2007).

The design method used to develop a new product can have a big impact on the possibilities of the manufacturer to adopt a platform strategy. Some design methods might be better suited than others to this task, and some are even geared towards that goal explicitly. Different product platform design approaches (top-down/business oriented, bottom-up/technically oriented), have been proposed, for example (Johannesson et al., 2017) explore the use to an approach based on object orientation and function modelling. The use of modularity for platform design was discussed by Hölttä-Otto (2005).

Modelling approaches can vary depending on the design method used, for example the Modular Function Deployment (MFD) method (Erixon, 1998) focused on the creation of modular architectures. Design space exploration methods like Multi-Attribute Tradespace Exploration (MATE) (Ross et al., 2004) provide a way to propagate an utility function throughout different levels of design. The Flexible Product Platform Development process proposed by Suh et al. (2007) dealt with component decomposition. Multidisciplinary approaches like Set-Based Concurrent Engineering (SBCE) use models that integrate functions and components (Levandowski et al., 2014), focusing on the allocation of system function to physical elements. The Value-Driven Design (VDD) methodology (Isaksson et al., 2013), combined with the Concept Design Analysis (CODA) method (Woolley et al., 2001), attempts to strengthen the requirements establishing process, iterating at different levels.

The architecture, or internal structure, of the product platform has been modelled in several ways, like the Generic Product Modelling (GPM) (Erens and Wortman, 1996), the Generic Variety Structure (GVS) and Product Family Architecture (PFA) (Jiao and Tseng, 1999), the Generic Bill-Of-Materials (GBOM) (Jianxin Jiao et al., 2000), the Generic Product Structure (GPS) (Du et al., 2003b), Graph Grammars (Du et al., 2003a), and Module-Interface Graphs (Otto et al., 2016).

The interrelations between product structures and their effects has been modelled ([Hackl and Krause, 2017](#)), showing which effects are most likely occur when a certain modular product structure is used, and how this choice affects other phases of the product lifecycle.

Many metrics have been defined to grade product platforms and mass customization, including modularity, scalability, and commonality of components. As the cost is the most intuitively understood metric for any business endeavour, methods like the Product Architecture Assessment have been widely used in business management contexts for product architecture costing ([Fixson, 2006](#)). Two main variables studied in the literature are the commonality cost reductions ([Thyssen et al., 2006](#); [Farrell and Simpson, 2010](#)), and the product technical performance (i.e. product quality, product effectiveness). The use of product platforms was linked to the creation of value ([Meyer and Lehnerd, 1997](#)), and the existing research on the analysis of value during product development and value-driven design was captured by [Isaksson et al. \(2013\)](#) for the aerospace industry.

How easy it is for that basis to be reused and repurposed can be described as the “flexibility” of the platform, following definition of flexibility: “the ability to change or adapt with little penalty in time, cost, effort or performance” ([Upton, 1994](#)). Analysis of flexibility has been approached from many perspectives like from the management side by ([Jana et al., 2018](#)), or from a change viewpoint ([Bauer et al., 2015](#)). Other investigations in to the behaviour of systems exposed to change and the propagation of its effects has led to the development of mathematical models to predict the risk of the change ([Clarkson et al., 2004](#)). [Haubelt et al. \(2002\)](#) introduced a hierarchical graph model to formally model the flexibility and cost of a system. The AMISA project aimed to optimize systems’ architectures towards maximum lifecycle value by developing a quantification methodology for Design for Adaptability approaches ([Schrieverhoff et al., 2012](#)).

Two critical aspects of flexibility have been defined ([Buganza and Verganti, 2006](#)): the product flexibility and the development process flexibility. Both the strategic decision-making process that enables product flexibility and the product development process are intimately interwoven, and their common interfaces define the bulk of product flexibility. A lot of the recent research has been focused on the flexibility that electronic systems and software can enable in the automotive industry, and the current use of electronic and software architectures ([Pelliccione et al., 2017](#)).

[Kim and Moon \(2017\)](#) described “high sustainability, low risk to product redesign, and high commonality” as the three characteristics of a sustainable platform. Balancing the trade-off between economic efficiency of platforms versus platform effectiveness ([Agard and Bassetto, 2013](#)), and the number of product platforms based on that trade-off ([De Weck et al., 2003](#)) ([Seepersad et al., 2000](#)) has been extensively considered. [Mirshekarian \(2015\)](#), expanded the Time-Expanded Decision Networks framework proposed by [Silver and de Weck \(2007\)](#), addressing the evolvability problem (among other ilities, as described by [De Weck et al., 2012](#)).

The modelling of the product platform evolution and its lifecycle has been approached by using methods like the Architecture Roadmap, a close relative of the higher-level Technology Roadmap. More analytical methods exist, like the Epoch Syncopation Framework (ESF) ([Fulcoly et al., 2012](#)). At automotive OEMs, scoring and achievement charts/spreadsheets traditionally guide business decisions.

Multidisciplinary and multi-technological approaches, like a development architecture (DA) have been postulated ([Oh et al., 2019](#)) to link market, design, and production structures. The analysis and improvement of engineering design processes themselves in the automotive sector has also been described using complexity metrics ([Kreimeyer and Lindemann, 2011](#)).

The number of product platforms and their “under- or overdesign” (contrasted with the products derived from them) in a firm have been proposed as drivers of the trade-off between the cost of the platforms and the cost of deriving products from a customizable platform ([Van Den Broeke et al., 2015](#)).

However, there is still an open question regarding how to support decision making when introducing new technologies that risk intruding upon the existing platforms, so that their impact and value adding projections can be assessed early enough to make a difference.

3.2. Industrial use cases

A summary of the data gathered at VCG and VGTT is presented in Table 3, for the drivers of change (the introduction of a new technology), and the constraints (boundaries for the development teams

efforts) encountered during the current use cases and the previous individual experiences of the participants.

Table 3. Change drivers and constraints in automotive use cases

	Use cases

● Present, ○ Not discussed

Compared to 0, results in 0 show more specific challenges encountered by the development teams in their decision making contexts, and as such reflect better the internal discussions observed in the teams. The challenges present at each firm are compared with the existing literature regarding the obstacles to the introduction of new technologies in product platforms. Similarities between both cases highlight the commonalities in practice are very strong in the automotive sector, and more so for companies that share the same talent pool for their recruiting.

The issues mentioned most often were related to the integration of existing components and production processes, interface management, regulatory compliance and market trends. The most significant differences were related to the different disciplines involved in the use cases discussed, and their direct impact on the user experience.

The findings from the use case discussions show that the drivers for change as well as high level constraints also reported in literature are evident in the cases studies. More interestingly, several additional challenges were revealed, highlighting that there are several decision-impacting factors that

are less well understood. Together, the multi-disciplinary nature of such issues is one of the main reasons why the prevalent means to deal with these are man power intensive (i.e. meetings, issue escalation).

4. Discussion

In the present work, we investigated what are the challenges encountered when introducing a new technology into a product derived from a platform. Our goal was to categorize the findings from industrial use cases in conjunction with previous findings from the literature, and to better understand the connection to the expectations from practitioners.

A way of assessing the impact decisions regarding the flexibility of a product platform on the lifetime value that the platform delivers is to consider the flexibility (and associated concepts like scalability, etc.), as a core feature of any design being considered and analyse their contribution to all considered scenarios, including in risk analyses and considering any decision as a trade-off that includes them. It has been shown that embedding flexibility in the elements of an automotive platform can lower switching costs when challenged by varying demand, but the use case was based on traditional mechanical elements, missing the relations between non-neighbouring components.

We envision a situation “to be” where models are made available to the decision makers as soon as possible, instead of the current “as is” state of having the models developed late (if at all) during the development process. This would enable quicker, proactive decisions, instead of the usually slow and reactive current ways of working, and lead to also quicker and more optimal changes being introduced in the design of product platforms. Further areas of study are the relation between the product platform

structure and mitigation strategies against the disruption caused by new technology integration, modelling of interfaces dynamically and at different levels during the development process, and determination of what information to highlight when changes happen, to help the decision-makers.

5. Conclusion

We investigated the challenges found in the integration of new technologies into product platforms. Our findings highlight a normative gap in the current automotive literature on how to approach this process and overcome some of the current challenges, such as the early availability of value models to assess for example the impact of flexibility and other 'ilities' in the lifecycle value of product platforms. Providing the development teams model-based tools and methods can support the decisions regarding trade-offs between platform changes and platform flexibility. The methods available in the literature are not all well-known in industry, and in addition, there is little reported in literature on the assessment of trade-offs between the compliance to existing product and process platform, and the user utility/value offered by introducing new technologies.

Our vision for the future of these processes is to support decision makers with a model-assisted methodology, that mitigates the consequences of the current challenges. The valuable feature of the methodology will be the translation of the interfaces between disciplines from the domain level up to a decision-making level by means of the functions required by the components, enabling the assessment of the platform flexibility.

Acknowledgement

The funding for this work was provided by the VISIP project, co-funded by the Swedish Governmental Agency for Innovation Systems (VINNOVA), Volvo Cars Group (VCG) and Volvo Group Trucks Technology (VGTT).
